## Lab \#11: Respiratory Physiology

## Background

The respiratory system enables the exchange of $\mathrm{O}_{2}$ and $\mathrm{CO}_{2}$ between the cells and the atmosphere, thus enabling the intake of $\mathrm{O}_{2}$ into the body for aerobic respiration and the release of $\mathrm{CO}_{2}$ for regulation of body fluid pH . In this exercise, we will examine ventilation of the lungs to enable the exchange of air between the alveoli and the atmosphere, and also explore the rate of $\mathrm{CO}_{2}$ release from the lungs as a mechanism for controlling pH .

## Mechanics of Lung Ventilation.

Air flow into and out of the lungs is driven by pressure differences between the atmospheric air and air in the lungs. When atmospheric pressure exceeds intrapulmonary pressure, air flows into the lungs, and when intrapulmonary pressure exceeds atmospheric pressure, air flows out of the lungs. Changes in intrapulmonary pressure are driven by changing the volume of the lungs-per Boyle's Law, the pressure exerted by a given amount of gas at a constant temperature is inversely proportional to the volume of that gas. Thus increasing the volume of the lungs will decrease intrapulmonary pressure, whereas decreasing lung volume will increase intrapulmonary pressure.

During tidal ventilation, air is inspired by contracting certain muscles in the walls and floor of the thoracic cavity (Fig 11.1). As the diaphragm contracts, it pulls downward and forward, whereas when the external intercostals contract, they lift the ribs upward and laterally.

Fig 11.1. Muscle contractions that drive tidal inspiration. From L. Sherwood, Fundamentals of Human Physiology. Brooks Cole

Fig 11.1. Relaxation of the inspiratory muscles drives tidal expiration (left), whereas forced expirations are driven by contraction of the expiratory muscles (right). From L. Sherwood, Fundamentals of Human Physiology. Brooks Cole.

The net result is an increase in the volume of the thoracic cavity. Since the lungs are adhered to the inner walls of the thoracic cavity, the lungs also expand. This decreases intrapulmonary pressure below atmospheric pressure, and air flows into the lungs along the pressure gradient.

Tidal expiration is driven by the relaxation of the muscles used to drive tidal inspiration (Fig 11.2). As the diaphragm moves upward and backward and the ribs move downward and inward the overall volume of the thoracic cavity is reduced. This compression of the thoracic cavity, in turn, elevates intrapulmonary pressure above atmospheric pressure, and air flows out of the lungs.
Additional amounts of air can be inspired or expired from the lungs with the contraction of additional muscles. Maximal inspirations are driven with contraction of muscles associated with the sternum and clavicle in addition to a full contraction of the diaphragm and external intercostals. Air can be forcibly expired from the lungs with contraction from the internal intercostals and a number of abdominal muscles (Fig 11.2).

## Lung Volumes and Capacities.

The amount of air contained in the lungs during ventilation can change considerably depending on what muscles are driving air flow and how forcefully they contract. The different amounts of air drawn into or out of the lungs by

Fig. 11.3. Illustration of a spirometer recording depicting measurements of the primary lung volumes (left) and the lung capacities (right)
contracting different groups of muscles are called primary lung volumes. Different combinations of the primary lung volumes, in turn provide us with lung capacities, which define either how much air is present in the lungs or how much air can be moved by the lungs under specific situations.

There are four primary lung volumes (Fig 11.3), defined as follow.

- Tidal volume $\left(V_{T}\right)$. The tidal volume is the amount of air inspired (or expired) during normal tidal breathing. At rest, tidal volume in healthy adult men is approximately 500 ml , and about 400 ml in women. Tidal volume increases with activity to accommodate increased need for gas exchange.
- Inspiratory Reserve Volume (IRV). The inspiratory reserve volume is the volume of air that can be maximally inspired above the volume inspired tidally. Average IRV measurements at rest for men and women are approximately 3100 ml and 2400 ml , respectively. IRV decreases with exercise.
- Expiratory Reserve Volume (ERV). The expiratory reserve volume is the maximum volume of air that can forcibly expired beyond a normal tidal expiration. Average ERV at rest is approximately 1200 ml for men and 900 ml for women at rest. Like IRV, the ERV decreases when exercising.
- Residual Volume (RV). The residual volume is the amount of air that remains in the lungs following a maximal expiration, and can only be forced out of the lungs by collapsing the lungs. The RV for men is approximately 1200 ml and approximately 900 ml in women.

There are also four lung capacities, each of which is the sum of two or more primary lung volumes.

- Total Lung Capacity (TLC). The total lung capacity is the maximum amount of air that can be held within the lungs at one time, and is the volume of air in the lungs following a maximal inspiration. TLC is the sum of all four primary volumes $\left(T L C=I R V+V_{T}+E R V\right.$ +RV ).
- Vital Capacity (VC). The vital capacity is the maximum amount of air that can be exchanged between the lungs and atmosphere in a single breath, and is the volume of air that can be forcibly expired from the lungs following a maximal expiration. The vital capacity is the sum of the three primary volumes that can be directly exchanged with the atmosphere ( $\mathrm{VC}=\mathrm{IRV}+\mathrm{V}_{\mathrm{T}}+\mathrm{ERV}$ ).
- Inspiratory Capcity (IC). The inspiratory capacity is the maximum amount of air that can be inspired following a normal tidal expiration. It is the sum of the inspiratory reserve volume and the tidal volume ( $\mathrm{IC}=\mathrm{IRV}$ $+\mathrm{V}_{\mathrm{T}}$ ).
- Functional Residual Capacity (FRC). The functional residual capacity is the volume of air that remains in the lung following a normal tidal expiration. It is the sum of the expiratory reserve volume and the residual volume ( $\mathrm{FRC}=$ ERV + RV).

## Measurements of Tidal Ventilation.

The amount of air exchanged between the lungs and the atmosphere during tidal breathing is

Fig 11.4. Illustration of a spirometer recording measuring forced expiratory volume.
determined influenced how much air is exchanged in each breath (the tidal volume) and how frequently breaths are take (the breathing rate). Measurements of tidal ventilation, therefore, must take both of these factors into account. One simple measurement of tidal ventilation is the minute volume $\left(\mathrm{V}_{\mathrm{M}}\right)$, which is the volume of air inspired through tidal breathing during in a one minute period of time. Minute volume is simply the product of the tidal volume $\left(\mathrm{V}_{\mathrm{T}}\right)$ and the breathing rate $(f)$

$$
\mathrm{V}_{\mathrm{M}}=f \times \mathrm{V}_{\mathrm{T}}
$$

The minute volume, however, overestimates the amount of air that is available for gas exchange. This is because not all of the air flowing into the lungs during inspiration flows into the alveoli; some of this air accommodates the increased volume of the respiratory passages during inspiration, and since these passages are not designed for gas exchange with the blood, they are considered to be physiological "dead space". A better measurement for the amount of air flowing over the respiratory surfaces during tidal ventilation is alveolar ventilation $\left(\mathrm{V}_{\mathrm{A}}\right)$, sometimes called the minute alveolar volume, which is the amount of air entering the alveoli in a one minute period. Alveolar ventilation is calculated using a similar equation to that of the minute volume except that it corrects for the volume of the dead space:

$$
\mathrm{V}_{\mathrm{A}}=f \times\left(\mathrm{V}_{\mathrm{T}}-\mathrm{V}_{\mathrm{DS}}\right)
$$

where $\mathrm{V}_{\mathrm{DS}}$ is the volume of the dead space (estimated to be $1 / 3$ of the resting tidal volume).

## Air Flow Measurements.

Efficient air exchange between the lungs and the atmosphere requires a) that the lungs be able to change volume effectively and b) air can pass through the respiratory passageways with relative ease. The ability of a person's lungs to change in volume is reflected in their vital capacity measurement-individuals with larger vital capacities can change the volume of their lungs more that can those with smaller vital capacities. The ability of air to flow through the respiratory passages, in contrast is reflected in a measurement called the forced expiratory volume $\left(\mathrm{FEV}_{\mathrm{t}}\right)$, which is the percentage of the vital capacity that, after a maximal inspiration, can be forcibly expired in $t$ seconds (Fig 11.4). $\mathrm{FEV}_{\mathrm{t}}$ can be calculated as the ratio of air forcibly expired in a designated time interval ( $\mathrm{V}_{\mathrm{t}}$, not to be confused with tidal volume, $\mathrm{V}_{\mathrm{T}}$ ) divided by the vital capacity (VC) and converted into a percentage.

$$
\mathrm{FEV}_{\mathrm{t}}=\frac{\mathrm{V}_{\mathrm{t}}}{\mathrm{VC}} \times 100 \%
$$

A young adult can typically expire roughly $80 \%$ of their vital capacity within one second, $94 \%$ within two seconds, and $97 \%$ within three seconds.

Vital capacity and $\mathrm{FEV}_{\mathrm{t}}$ measurements can be used to diagnose various types of air flow disorders. Abnormally low $\mathrm{FEV}_{\mathrm{t}}$ measurements (less than $90 \%$ the value predicted for an individual based on their age) may be indicative of an obstructive disorder. In an obstructive disorder, air flow through the respiratory passages is impeded by a narrowing of those passages, thus increasing resistance to air flow. Bronchiolar secretions and constriction of air passageways (See Fig 11.5) are common causes of obstructive disorders. On the other hand, abnormally low vital capacity (less than $80 \%$ the predicted value based on age, sex, and body size) may be indicative of a restrictive disorder. In a restrictive disorder, the lungs are unable to

Fig 11.5. Asthma is an example of an obstructive lung disorder. Smooth muscle contraction in the respiratory passages reduce the diameter of the airways, increasing resistance to air flow through them. Image from http://www.drgreene.org/images/cg/19346.jpg
change volume enough to allow adequate air flow into and out of the alveoli. This could be caused by a loss of elasticity of the tissue, fluid within the alveoli, or an increase in the dead space of the lungs (see Fig 11.6). Note that a particular lung pathology could be both obstructive and restrictive. For example, in emphysema (Fig 11.7), the alveolar walls break down. This decreases the elasticity of the lungs, increases the dead space, and decreases the vital capacity, and is thus a restrictive disorder. The breakdown of the alveoli, however, also reduces structural supports for the bronchioles, thus the bronchioles may narrow or even collapse, creating obstruction to air flow.

Fig 11.6. X rays of normal lungs (left) and lungs with pulmonary fibrosis (right). Pulmonary fibrosis, or scarring of the lung tissue, is a restrictive disorder. Interstitial spaces between the alveoli are filled with fibrous tissue, thus restricting the ability of the alveoli to expand. Moreover, the alveoli are often inflamed, resulting in fluid within the alveoli that reduce alveolar volume and increase diffusion distances. Images from alice.ucdavis.edu/ IMD/420C/films/cxr4.htm

Fig. 11.7. Cross section of a lung with emphysema. Note the numerous cavities formed by the collapse of alveolar walls. The result is an elevation in residual volume, a decrease in vital capacity, and elevated resistance to air flow in the respiratory passages. ## Carbon Dioxide Exchange and pH Balance.

$\mathrm{CO}_{2}$ is an important factor in the regulation of pH in the human body. This is because $\mathrm{CO}_{2}$ in solution can reversibly react with water to form carbonic acid.

$$
\mathrm{CO}_{2}+\mathrm{H}_{2} \mathrm{O} \leftrightarrow \mathrm{H}_{2} \mathrm{CO}_{3}
$$

Carbonic acid, in turn, may dissociate into bicarbonate and free hydrogen ion, in turn elevating the $\left[\mathrm{H}^{+}\right]$of the solution and lowering pH .

$$
\mathrm{H}_{2} \mathrm{CO}_{3} \leftrightarrow \mathrm{H}^{+}+\mathrm{HCO}_{3}^{-}
$$

$\mathrm{CO}_{2}$ is transported in the blood stream by three different means: as dissolved $\mathrm{CO}_{2}$ gas in the plasma, by binding to hemoglobin in the erythrocytes, and in the form of bicarbonate in the blood plasma. Both methods of transporting $\mathrm{CO}_{2}$ in the plasma can influence the pH of the plasma.

Most of the bicarbonate present in blood plasma is not a result of spontaneous reactions

Fig 11.8. Diagram illustration the three means of $\mathrm{CO}_{2}$ transport in the blood. Note that some of the $\mathrm{CO}_{2}$ dissolved in the plasma can react spontaneously with water to form carbonic acid. Thus increased $\mathrm{CO}_{2}$ in the plasma tend to decrease plasma pH through increased carbonic acid formation.
between $\mathrm{CO}_{2}$ and $\mathrm{H}_{2} \mathrm{O}$, but is manufactured by the erythrocytes (Fig 11.8). Roughly 90\% of the $\mathrm{CO}_{2}$ released from the cells is absorbed by the erythrocytes. About $20 \%$ binds to hemoglobin, whereas the remaining $70 \%$ reacts with water to form carbonic acid in a reaction catalyzed by the enzyme carbonic anhydrase. The carbonic acid formed subsequently dissociates into $\mathrm{H}^{+}$and bicarbonate. $\mathrm{H}^{+}$binds to specific amino acid side chains on the hemoglobin, whereas the bicarbonate is transported out to the blood plasma. The bicarbonate formed can act as a buffer against pH changes due to the introduction of other acids, since increases in $\left[\mathrm{H}^{+}\right]$will tend to promote the binding of $\mathrm{H}^{+}$to bicarbonate.

The remaining $10 \%$ of the $\mathrm{CO}_{2}$ released by the cells can also influence blood pH . Some of this dissolved $\mathrm{CO}_{2}$ will spontaneously react with water to form carbonic acid, which in turn will dissociate into $\mathrm{H}^{+}$and bicarbonate. Note that in this case the $\mathrm{H}^{+}$is released into the plasma. The more dissolved $\mathrm{CO}_{2}$ present in the blood, the more $\mathrm{H}^{+}$will be released into the plasma, and the lower the pH will be. Thus regulation of dissolved $\mathrm{CO}_{2}$ levels in the plasma is an important component of body fluid pH regulation. By modifying tidal ventilation and subsequent $\mathrm{CO}_{2}$ release into the atmosphere, dissolved $\mathrm{CO}_{2}$ levels in the blood can be tightly regulated and thus blood pH can be tightly regulated.

Fig 11.9. The Labscribe setup for measuring lung ventilation.

## Experiment I: Lung Ventilation.

## A. Tidal volume, breathing rate, and alveolar ventilation measurements

1. Place a disposable cardboard mouthpiece over one of the ends of the spirometer flow head attached to the iWorx unit.
2. Go to the computer screen, and be sure the software (LabScribe) is running (Fig 11.9). The top tracing will display voltage changes from the transducer-ignore it for our exercise. The lower tracing converts these changes in voltage into volume changes, and you will be using this tracing for all of your measurements. Change the display time to 60 sec by selecting the EDIT menu from the top, then PREFERENCES, then enter the desired display time in the middle box of the top line.
3. Click "START" in the top right corner of the screen.
4. The subject should wait five seconds before beginning to breathe through the mouthpiece so the instrument can equilibrate correctly. Have the subject place the mouthpiece fully in their mouth and
pinch their nostrils closed so that they breathe only through their mouth. The subject should breathe through the mouthpiece normally for $\sim 70$ seconds (your can keep track of this by the meter in the top left corner of the screen, then click "STOP" at the top right of the screen. If the tracing "stairclimbs" (i.e., keeps moving progressively up or down) during your recording ask your instructor for assistance.
5. If the tracing on the lower screen is reversed (i.e., the tracing dips when the person breathes in), right click on the lower screen and select "INVERT"
6. Count the number of inspirations made during the last 60 seconds of the recording (i.e., what is on the screen) to determine the respiratory frequency for this individual (see Fig 11.10).
7. Select a single tidal breath in the recording. Drag one of the blue lines at the far right edge of the tracing over to the low point of this tidal breath, and drag the other blue line over to the peak of the tracing (see Fig 11.10). The difference in volume between these to points, showing just above the tracing to the right, is the tidal volume $\left(\mathrm{V}_{\mathrm{T}}\right)$. Measure the tidal volume for three separate breaths and record the average of these values.
8. Calculate the alveolar ventilation using the respiratory frequency, the average tidal volume, and assuming that the volume of

Fig. 11.10. Positioning Reference lines for determination of Tidal Volume $\left(\mathrm{V}_{\mathrm{T}}\right)$ the dead space $\left(\mathrm{V}_{\mathrm{DS}}\right)=1 / 3$ the average resting tidal volume. Remember: $\mathrm{V}_{\mathrm{A}}=\mathrm{RF} \times\left(\mathrm{V}_{\mathrm{T}}-\mathrm{V}_{\mathrm{DS}}\right)$
9. Have the subject exercise moderately by having them run up and down a staircase 2-3 times then run back to the lab (they should be fairly winded when they return). As soon as they return to the lab, repeat the procedures above and determine the respiratory frequency, tidal volume, and alveolar ventilation during exercise. NOTE: use the estimate for $\mathrm{V}_{\mathrm{DS}}$ calculated from resting tidal volume to calculate alveolar ventilation.

## B. Lung volumes, capacities, and forced expiratory volume.

1. Click "START" in the top right corner of the screen.
2. After waiting five seconds, have the subject place the mouthpiece in their mouth and pinch their nostrils closed so that they breathe only through their mouth. The subject should take five normal tidal breaths through the mouthpiece with their noses pinched closed as you record. When they have expired their fifth tidal breath, they then should inspire as much air as they possibly can (the rest of the group should cheer them on), then expire as much air as quickly and forcibly as they possibly can (again, cheer them on as they are doing this). The subject must make sure their nostrils are pinched closed so that air escapes only through the mouthpiece. Only after the subject cannot force any more air out of their lungs should they remove the mouthpiece.

Fig. 11.11. Positioning Reference lines for determination of Tidal Volume $\left(\mathrm{V}_{\mathrm{T}}\right)$

Fig. 11.12. Positioning Reference lines for determination of Inspiratory Reserve Volume (IRV) .

Fig. 11.13. Positioning Reference lines for determination of Expiratory Reserve Volume (ERV).

Fig. 11.14. Positioning reference lines for determination of Vital Capacity (VC).
3. If the tracing on the lower screen is reversed (i.e., the tracing dips when the person breathes in), right click on the lower screen and select "INVERT". You may also want to change the display time to 30 sec instead of 60 seconds. You may do so by selecting the EDIT menu from the top, then PREFERENCES, then enter the desired display time in the middle box of the top line.
4. Using the blue lines, determine the tidal volume $\left(\mathrm{V}_{\mathrm{T}}\right)$ for this tracing based on the tidal breath immediately before the maximal inspiration (see Fig. 11.11). It should be similar to the average tidal volume recorded for that individual earlier.
5. Determine the inspiratory reserve volume (IRV) by measuring the difference in volume from the peak of the tidal inspiration to the peak of the maximal inspiration (see Fig. 11.12).
6. Determine the expiratory reserve volume (ERV) by measuring the difference in volume from the base of the tidal expiration to the base of the maximal expiration, per Fig. 11.13.
7. Measure the vital capacity (VC) by measuring the difference in volume from the peak of the maximal inspiration to the base of the maximal expiration, per Fig. 11.14. Compare this value with the subject's predicted vital capacity (based on their age, sex and height, see Appendix).
8. Calculate the inspiratory capacity (IC) by either a) subtracting the expiratory reserve volume from the vital capacity or b) adding the tidal volume and inspiratory reserve volumes together.
9. Estimate the residual volume (RV) and total lung capacity (TLC) for the subject by multiplying the volume of the vital capacity by the values based upon age given in Table 11.1.
10. Calculate the functional residual capacity (FRC) by adding the residual volume and the expiratory reserve volume together.

Table 11.1. Equations for estimating residual volume (RV) and total lung capacity (TLC) from measured vital capacity.

| Age | Estimated Residual <br> Volume | Estimated Total Lung <br> Capacity |
| :---: | :---: | :---: |
| $16-34$ | $0.250 \times$ Vital Capacity | $1.250 \times$ Vital Capacity |
| $35-49$ | $0.305 \times$ Vital Capacity | $1.305 \times$ Vital Capacity |
| $50-69$ | $0.445 \times$ Vital Capacity | $1.445 \times$ Vital Capacity |

Lab \#11: Respiration

Figure11.15. Positioning reference lines for determination of the volume of air forcibly expired in 1 second $\left(\mathrm{V}_{1}\right)$. Note that the left-hand line needs to be positioned at the start of the forced expiration, then the right-hand line should be positioned as close to 1.000 sec after the left-hand line as possible (arrow).

## C. Forced Expiratory Volume

To calculate the forced expiratory volume $\left(\mathrm{FEV}_{1}\right)$, return to the recording of the vital capacity from the previous experiment. Place one of the blue lines on the peak of the maximal expiration at the exact point at which the person begins to exhale (see figure below). Position the second line to the right of the first so that the time meter in the top left hand corner of the screen ("T2-T1") is as close to 0:0:1.000 ( 1 second) as possible (see Fig 11.15). Record the volume of air expired in 1 second (upper right hand of lower tracing), then divide this value by the vital capacity, and convert to a percentage per the following equation.

$$
\mathrm{FEV}_{1 \mathrm{sec}}=\mathrm{V}_{1 \mathrm{sec}} / \mathrm{VC} \times 100 \%
$$

Table 11.2. Predicted $\mathrm{FEV}_{1 \text { sec }}$ values.

| Age | Predicted FEV1sec (\%VC) |
| :---: | :---: |
| $18-29$ | $80-82 \%$ |
| $30-39$ | $77-78 \%$ |
| $40-44$ | $75.50 \%$ |
| $45-49$ | $74.50 \%$ |
| $50-54$ | $73.50 \%$ |
| $55-64$ | $70-72 \%$ |

From S.I. Fox, Laboratory Guide to Human Physiology, $9^{\text {th }}$ ed, McGraw Hill.

Compare the value obtained with the subject's predicted $\mathrm{FEV}_{1}$ values (based on age) in Table 11.2.

Fig 11.16. Progressive changes in the color of a phenolphthalein solution as $\mathrm{CO}_{2}$ is added to the solution and pH decreases from alkaline to neutral pH . Images from http://www.chemistry.wustl.edu/~courses/genchem/Labs/AcidBase/phph.htm.

## Experiment II: $\mathrm{CO}_{2}$ Production and Acid-Base Balance.

## A. Elevated Blood $\left[\mathrm{CO}_{2}\right]$ and its Effect on $\mathbf{~ p H}$

Obtain a pair of beakers containing $\sim 150-200 \mathrm{ml}$ of our test solution, which consists of distilled water, a small amount of NaOH to generate a weakly alkaline pH , and a few drops of phenolphthalein. The color of phenolphthalein changes with pH ; at a $\mathrm{pH}>7.0$, phenolphthalein is pink, but below pH 7.0 it is colorless. Place two straws into one of the two beakers. Have the subject place the straws in their mouth and start timing. The subject should breathe tidally inspiring through the nose then expiring through their mouth, blowing bubbles into the solution. Be sure to breathe as normally and tidally as possible (this is not a bubble-blowing contest!). Time how long it takes for the solution to lose all pink coloration (Fig 11.16). Once completed, have the person go for a quick run outside or up and down the staircase to elevate their respiration (they should be panting when they return). Immediately give them the second beaker of solution and repeat the procedure. Note any difference in the time it takes to turn the solution clear.

## B. Reduced Blood $\left[\mathrm{CO}_{2}\right]$ and its Effect on Respiration

Have someone in your lab group sit quietly for one minute, then record their resting breathing rate for 30 sec . Multiply this value by two to obtain the breathing rate (breaths $/ \mathrm{min}$ ) and record. Then have them hyperventilate for 10 seconds, increasing both tidal volume and breathing frequency as much as possible. Once they have completed their hyperventilation, record their breathing rate once again for a period of 30 sec and record the breathing rate in breaths $/ \mathrm{min}$. Note any difference in breathing rate.

## APPENDIX: Predicted Vital Capacity - Females
